PROJECT: LFST
subject: Elasticity of long ropes

$$
\begin{gathered}
\text { The effective elasticity, E }{ }_{c} \text {, of a long rope, } \\
======================================= \\
\text { sagging under its own weight } \\
===========================
\end{gathered}
$$

S. von Hoerner

Some structures may use long ropes, for example a guyed tower does. The stiffness of such a structure depends on the modulus of elasticity, $E$, of the material used, but it also depends on the "sag" of the ropes which decreases the stiffness. We still can treat a long rope in the same way as any solid member, if we define for the rope an "effective modulus of elasticity", $E_{s} \leq E$, where $E$ is given as the elasticity of the material used, but $E_{s}$ is a function of the sag. Since $I$ could not find a formula of this type in a few textbooks, and since this question might be important for very large structures, I give the following derivation.

1. We approximate the Catenary of a hanging rope by a circle (assuming a tight rope). Then

$$
\left.\begin{array}{l}
s=2 r \beta \\
\ell=2 r \sin \beta
\end{array}\right\} \quad \frac{s}{\ell}=1+\frac{1}{6} \beta^{2} \pm \cdots
$$

2. In equilibrium, we have

$$
\begin{equation*}
F_{1}=\frac{1}{2} \rho l Q \cos \alpha \tag{2}
\end{equation*}
$$

with $\rho=$ density of material and $Q=$ cross section. We call $\ell_{0}$ the undeformed length of the rope, which means that

$$
\begin{equation*}
\frac{s}{l_{0}}=1+\frac{F}{Q E} \tag{3}
\end{equation*}
$$

and we make use of

$$
\begin{equation*}
\beta \approx \tan \beta=F_{1} / F \tag{4}
\end{equation*}
$$

With (20, (3) and (4), equation (1) can be written as

PROJECT:
SUBJECT:

$$
\begin{equation*}
\frac{F^{3}}{Q E}=\left(\frac{l}{l_{0}}-1\right) F^{2}+\frac{1}{24} \frac{l}{l_{0}}\left(\rho l_{Q} \cos \alpha\right)^{2} . \tag{5}
\end{equation*}
$$

3. The effective elasticity we now define as

$$
\begin{equation*}
E_{s}=\frac{\ell}{Q} \frac{d F}{d l} . \tag{6}
\end{equation*}
$$

From ( 5 ) we find $\mathrm{dF} / \mathrm{d} \ell$, and after neglecting all terms of higher order we obtain

$$
\begin{equation*}
E_{s}=E\left(1-\frac{1}{12} \frac{E f^{2} \ell^{2} Q^{3}}{F^{3}} \cos ^{2} \alpha\right) \tag{7}
\end{equation*}
$$

4. In order to show more clearly what equation (7) means, we define two quantities:

$$
\begin{array}{ll}
\text { critical length (material constant) } & l_{c}=\frac{S^{3 / 2}}{\rho E^{1 / 2}} \\
\text { safety factor (free choice) } & q=\frac{Q S}{F} \geq 1 \tag{9}
\end{array}
$$

where $S=$ maximum allowed stress of material. With these definitions, equation (7) reads finally

$$
\begin{equation*}
E_{s}=E\left\{1-\frac{1}{12} q^{3}\left(l / \ell_{c}\right)^{2} \cos ^{2} \alpha\right\} \tag{10}
\end{equation*}
$$

5. Taking, for example, high-strength Bethlehem ropes, we have $E=23 \times 10^{6}$ psi and $S=$ Yield $/ 1.85=81 \times 10^{3} \mathrm{psi}$, which gives

$$
\begin{equation*}
l_{c}=430 \mathrm{~m}=1410 \mathrm{ft} \tag{11}
\end{equation*}
$$

6. As an example, we assume $\alpha=45^{\circ}$, and we allow $q=2$ (for taking up wind forces). Equation (10) then becomes

$$
\begin{equation*}
E_{S}=E\left\{1-(\mathcal{L} / 744 m)^{2}\right\} \tag{12}
\end{equation*}
$$

If we apply this to the guyed tower in Fig. 5 of my Flat-Antenna Report (No.7), we find that the modulus of elasticity goes down by only $4 \%$.

PROJECT:

SUBJECT:
7. The critical length, $l_{c}$, depends strongly on the maximum allowed stress, $S$, of the material used. It gets very short for normal steel, which means that high-stress steel should be used for long, solid rods, like tensioned diagonals or long guy rods. A few examples are given in the table below.

| material | Yield | E |  | $\boldsymbol{C l}_{\text {c }}$ |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | $10^{3} \mathrm{psi}$ | $10^{6} \mathrm{psi}$ | meter | feet |  |
| prestreched wire rope | 150 | 23 | 430 | 1410 |  |
| solid steel rod | 100 | 30 | 268 | 880 |  |
|  | 50 | 30 | 94 | 310 |  |
|  | 30 | 30 | 44 | 140 |  |

The figure below shows the effective elasticity as a function of length, according to formula (10), for which we adopted the values

$$
\begin{array}{ll}
\alpha=45^{\circ} & \text { elevation angle above horizontal } \\
q=1.5 & \text { safety factor (stress }=S / 1.5=\text { Yield/2.77) }
\end{array}
$$
