# On P-band Observations with the VLBA 

Eric W. Greisen

March 1, 2024

#### Abstract

The VLBA has a little-used mode of observation that produces 3 or more spectral windows at 90 cm and, optionally, one at 50 cm wavelength. For this Memo, three science projects and two data quality observations were examined. The results suggest that, while the VLBA is not particularly sensitive in this mode, useful results can be obtained with some effort.

## 1 Introduction

In two of the science data sets, the P-band system of the VLBA produced 4 spectral windows, 3 at about 90 cm wavelength $(0.315,0.323,0.331 \mathrm{GHz})$ and one at about 50 cm wavelength $(0.607 \mathrm{GHz})$. Each spectral window is rather narrow ( 8 MHz total). The outer channels at 50 cm have very little amplitude, so the usable bandwidth at 600 MHz is only about 5 MHz . One data set from project BS309 (PI Carlo Stanghellini) was an attempt to observe a "young" radio galaxy with both diffuse and mas-scale emission. It was observed 02 August, 2022 with 16 spectral channels per SPW. The other data set, BG279B at P band, had Neeraj Gupta as PI and sought to map a powerful FRI-type quasar at $\mathrm{z}=2.1$ embedded in an HI halo. It was observed 29 July 2022 with 64 spectral channels per SPW. (Note that the majority of BG279 was observed at C band and not considered here.)
The third science data set produced 4 SPWs all at $90 \mathrm{~cm}(0.31225,0.32025,0.32825,0.33625 \mathrm{GHz})$. Each has 64 spectral channels separated by 0.125 MHz . Project BM486A (PI Emmanuel Momjian) was an attempt toq resolve an extremely powerful radio-loud quasar at z 5.1. There are two P-band correlation files in the archive, the slightly larger one has "calib" added to the name. Both were examined for this study. The P-band data were observed on 18 February 2019.

The two Data Quality runs used different setups. DQ2318 used 4 MHz bandwidth spectral windows at $320.8,324.8,328.8$, and 608.8 MHz and only 8 spectral channels per SPW. It was observed on 28 May 2023. The second DQ data set, DQ2229 used two different setups and was observed 4 August 2022. The first data set was similar to BS309, but at frequencies $0.32075,0.32475,0.32875$, and 0.60875 GHz with 8 spectral channels each 0.5 MHz wide and all 4 polarizations. The second DQ2229 data set had 8 SPWs each with 16 spectral channels 0.5 MHz in width and only the LL correlation. The SPWs ranged from 0.29275 to 0.34875 GHz.

## 2 DQ2318

The data of DQ2318 consists of a single 6-minute scan on J1642+3948. BR was flagged for sub-reflector focus error for the whole run. Tsys was well behaved for most antennas including BR, but SPWs 3R and 4R at KP, 4 R and 4 L at LA, 3 R at MK, all SPWs at OV are in the kilo or mega Kelvin range. The Tsys at NL appears rather low compared to the others and PT 2R is probably 2 to 3 times too high. The first Tsys value in the

Table 2: SNRMS output for TY table from DQ2318 50cm
scan was quite a bit higher than the others for several antennas. The Tsys values are summarized using SNRMS in Table 1 and Table 2.

Examining autocorrelation data for evidence of RFI we find spikes at KP SPW 3 R and L channel 7 (0.3318), MK SPW 3 R and L channel 4 ( 0.3303 ), NL SPW 3 R and L channel 8 ( 0.3323 ), and PT SPW 1 L channels 2 and 3 ( $0.321 .3,0.321 .8$ ). BR was flagged, SC had no valid autocorrelations, and OV lost all of R and SPW 1 L also. OV SPW 2 L may have RFI in channels 7 and $8(0.3278,0.328 .3)$. No spikes were seen in the 50 cm data. The autocorrelation signals are quite variable over time for KP SPW 3 and moderately variable for MK SPW 3 and OV SPW 1.

The target source was well detected on all baselines with those to OV being rather noisy and with considerable evidence of resolution by the longest baselines. Delay and bandpass calibration did not seem to be called for. After standard VLBI calibration (with an edited TY table) and SPLIT, CALIB run with a point source at the origin converged on almost all solutions. Self-cal started with Clean flux density of 4.1 Jy , rose to 4.7 and, with amplitude and phase, dropped to 3.34 Jy . The image rms began at $0.110 \mathrm{Jy} / \mathrm{beam}$ and dropped to $0.017 \mathrm{Jy} /$ beam.

## 3 DQ2229a

The first of the DQ2229 data sets consists of a single 6-minute scan on J2148+0657 with three SPWs at about 90 cm and one at 50 cm . BR is flagged over the full time for sub-reflector focus error and KP is missing. The source is well detected on all baselines with evidence of resolution on baselines to MK and SC at 90 cm . Autocorrelations at 90 cm show RFI at 330 MHz at MK in both polarizations, at the highest frequency at NL both polarizations, and a weaker signal above 320 MHz at PT in L polarization. No obvious RFI is found in the limited 50 cm data.

Tsys is relatively normal except LA at 50 cm (Mega K) and PT SPW 2R (kilo K). MK is high at SPW 3 and NL oddly low except SPW 3L and 50 cm . Without fixing any Tsys, the data responded to the normal calibration sequence as one would hope. After SPLIT, CALIB was run with a point source at the origin to obtain an initial phase calibration. Imaging at 90 cm then produced a Clean flux density of 3.93 Jy with image noise of $0.017 \mathrm{Jy} /$ beam reduced to $0.008 \mathrm{Jy} /$ beam with amplitude and phase self-cal. At 50 cm , self-cal raised the

Figure 1: J2148+0657 self-cal images at 90 cm (left) and 50 cm (right). Note that self-cal forces the brightest point in the source to the center of the image. The apparent alignment of the two images should therefore not be believed.
total flux density slightly to 3.83 Jy while reducing the noise from $0.011 \mathrm{Jy} / \mathrm{beam}$ to $0.006 \mathrm{Jy} / \mathrm{beam}$. The resulting images are shown in Figure 1.

## 4 DQ2229b

The second of the DQ2229 data sets consists of two 3-minute scans on J2253+1608 with eight SPWs at about 90 cm spanning 64 MHz in LL polarization. The response is weak in SPW 1 and the last 6 channels in SPW 8, making the useful bandwidth 53 MHz . BR has useful data in this data set and KP is still missing. RFI makes a mess of SPWs 6 and 7, centered on 340 MHz , at LA. SPW 5 around 330 MHz is bad at MK, NL has an RFI spike just above 330 MHz , OV has RFI spikes throughout, and PT has an RFI spike at 300 MHz . The other antennas' autocorrelations are relatively clean. OV is relatively clean in the first data set and a terrible mess in this immediately following data set.

Tsys in SPW 1 is very high (kilo K) on all antennas. SPW 8 tends to be higher than the other SPWs on all antennas. PT has high and quite variable Tsys and OV has mega $K$ of both signs. SPW 7 at LA has a bad point (-49 kilo K). UVFLG was used to flag all of SPW 1, the highest 6 channels in SPW 8, and all of OV. SNEDT was used to flag bad Tsys values before they were used in calibration. Standard calibration was done except that FRING was told to get a single solution covering all SPWs at the VLBAMPCL step. The data were SPLIT and then made phase coherent with a point source at the origin by CALIB. Self-cal imaging changed the total flux density from 9.8 Jy to 10.6 Jy , with the noise going from $0.085 \mathrm{Jy} / \mathrm{beam}$ to $0.025 \mathrm{Jy} / \mathrm{beam}$. The source is somewhat extended to the northwest as seen in Figure 2.

Figure 2: J2253+1608 self-cal images at 90 cm .

## 5 BS309

BS309 was observed on August 2, 2022. Primary calibration sources were 4C39.25, 3C273, J1331+3030 (3C286), 3C345, and 1358+624. The phase reference source J1408+2831 was observed with 2 different source numbers while the target source was OQ208. The standard frequency setup was used with $160.5-\mathrm{MHz}$ spectral channels per SPW. Antenna 2 was Effelsberg and did not have Tsys values. It was ignored.

Examining the Tsys tables at 90 cm , seriously corrupt values are found for BR SPW 1 R and L, all SPWs for MK and OV, and all R SPWs and 3L for PT. SNEDT may be used to flag out the bad values leaving generally reasonable Tsys. Serious time-dependent disturbances in Tsys are seen for MK SPW 2 R and L, NL, PT, and SC after the editing. At 50cm, LA and OV have bad values in R and L, NL has bad values only in R. SNEDT leaves almost no values for LA and flags the last several hours of OV. The Tsys values after flagging are summarized using SNRMS in Table 3 and Table 4.
VBRFI is a task designed to examine autocorrelation spectra for evidence of RFI. It determines the mean and rms as a function of spectral channel in each scan and polarization. It then sums across scans and polarizations to determine the mean autocorrelation, rms , and $\mathrm{rms} /$ mean spectra. A sample from the 90 cm data set is plotted in Figure 3. Note the RFI signal in both the autocorrelation and the time variability at 319.25 and 328.25 MHz . SPW 3 is poorly behaved and apparently variable in time. BR, LA, and OV show clear RFI signals as well. There seems to be little RFI in the 50 cm data. A possible signal is seen at 610 MHz at OV. Note that spectral channels $1-3$, and $14-16$ in the 50 cm data set have essentially zero amplitude and have been flagged at the start.

I then attempted to calibrate these data. Using one scan on 3C286, VLBAMPCL converged on all antennas and polarizations except HN L polarization which failed at both 50 cm and 90 cm . The bandpass computation failed for 50 cm HN L polarization. FRING was then run separately for each source. At 50 cm , it failed about $88 \%$ of the time on 4C39.25, J1408+2831, and OQ208. $50 \%$ on $1358+624,39 \%$ on $3 \mathrm{C} 345,29 \%$ on 3 C 286 , and $7 \%$ on 3C273. At 90 cm , FRING converged for most of the possible solutions for 3C273, 3C345, J1331+3030 and $1358+624$, but failed for $88 \%$ or more for J1408+2831 and OQ208. CALIB with a simple point source at the origin was tried for J1408+2831 but the solutions failed $90 \%$ of the time. 4C39.25 is normally a good VLB calibrator, but it was the first scan (only) in this data set and a total failure for calibration.

Table 5: Clean flux densities and rmses initially and after self-cal

Figure 4: VBRFI plot for antenna MK at 50cm in BG279B. The average autocorrelation spectrum is plotted at left and the rms spectrum is plotted at right.

The four primary calibrators were SPLIT, producing data sets with only half to two thirds as many visibility samples as in the input data set. They were then imaged and run through several rounds of self-cal. The Cleaned flux densities and rms for each are summarized in Table 5. Two methods were tried to deal with the bad Tsys values. In one, the bad values were flagged causing the associated data to be flagged. In the other, the bad values were replaced by apparently good values from nearby times. Imaging with the latter produced lower flux densities, suggesting that the data are bad when the Tsys are bad.

## 6 BG279B

The BG279B data set had the same 4 SPWs as BS309, but each SPW had 64 spectral channels each 0.125 MHz wide. Nine VLBA antennas were used, KP was missing. The source list was 3C273 as a primary calibrator, J1512-0905 as the phase reference calibrator, and J1538-1510 as the target source. At 50cm, the edge channels have little or no signal. Channels 1 through 14 and 56 through 64 were flagged at the beginning. At 50 cm , the delays were apparently quite small. At 50 cm , Tsys values reached Mega K for LA and IV, Kilo K for NL, and were quite time variable for SC. SNEDT was used to flag the bad values. RFI was seen in all 50 cm autocorrelations except NL. The spikes were every MHz and are due to the pulse cal presumably. They are illustrated in Figure 4. This "RFI" is not seen in the cross-correlation data.
At 90cm, the Tsys are sensible except for MK SPW 3, PT SPW 2R and all of OV. The Tsys values after flagging are summarized using SNRMS in Table 6 and Table 7. The autocorrelation spectra at 90 cm show a variety of spikes some of which are not due to the pulse cal. They are illustrated in Figure 5, where SC is omitted since it had no serious RFI spikes. SPW 3 L had some serious oscillations in some antennas. To illustrate this more clearly in Figure 6, the rms spectra from the autocorrelation data do show affects of the pulse cal but also significant time variability of actual RFI.

Table 7: SNRMS output for TY table from BG279B 50cm

Calibration of BG279B proceeded more or less normally. At 90 cm , FRING had 143 good solutions on 3C273 with 7 failures. J1512-0905 had 1143 good solutions with 69 failures. The target source J1538-1510 even succeeded two thirds of the time. At 90 cm , imaging of 3 C 273 started with a Clean flux density of 11.5 Jy which became 12.6 Jy after a number of rounds of self-cal in agreement with the flux density found in BS309. The image rmses went from $0.153 \mathrm{Jy} / \mathrm{beam}$ to $0.032 \mathrm{Jy} /$ beam after self-cal. J1512-0905 had 1.25 to 1.32 Jy Cleaned flux density with rms 0.008 to 0.002 Jy/beam. Applying the FRING solutions of J1512-0905 to the target did not allow the target to be detected. Applying CALIB to the target source with simply a point at the center got phase solutions for all but $0.1 \%$ of the samples. Imaging from there found two sources in the field with total flux density that went from 0.37 Jy to 0.49 but then dropped with amplitude/phase self-cal to 0.34 Jy. The image rms went 0.0019 to 0.00026 Jy /beam. It is shown in Figure 7.
At 50 cm , FRING essentially failed completely and normal "calibrated" output files had no visible sources. Using CALIB with phase only on the two calibration sources, about $90 \%$ of the possible solutions succeeded. Running SPLIT with this calibration, imaging of 3C273 worked rather well. The Cleaned flux density started as 19.9 Jy and was reduced to 17.6 Jy by 2 rounds of amplitude and phase self-cal. This is quite different from the flux density at 50 cm found in BS3909. The image rms started at $0.564 \mathrm{Jy} / \mathrm{beam}$ and dropped to 0.104 in the last round. Calibrator J1512-0905 had cleaned flux density of 1.27 Jy , rising to 1.40 Jy with self-cal. The image rms was $0.016 \mathrm{Jy} / \mathrm{beam}$ which dropped to $0.0068 \mathrm{Jy} / \mathrm{beam}$ with the amplitude self-cal. The target source was not detected in the SPLIT output file and CALIB was not able to get a solution for a point source at the origin ( $87 \%$ of the solutions failed).

## 7 BM486A

BM486A was observed on 18 February 2019 with primary calibrator 3C273, phase calibrator J1258-2219, and target source J1314-2020. Four SPWs were observed, all at roughly 90 cm wavelength. Tsys values were mostly reasonable except for SPWs 3 and 4 at KP and LA. Examining the Tsys statistics in Table 8 and Table 9 suggests that the noise tube calibration at $P$ band is suspect. NL is way too low for all SPWs while at PT the scales of the two polarizations differ by more than a factor of 2 . For most antennas, the plots of Tsys versus time are rather similar in all SPWs and polarizations, but the quoted scales are often rather different. This problem may also be seen in the other data sets examined here.

The initial calibration of BM486 went normally with an edited Tsys table and 3C273 as the calibration source.

Figure 6: VLBRF autocorrelation rms spectrum at 90 cm in BG279B for 2 antennas. The left plot shows the full range of values in LL polarization while the right plot shows a limited range of values in RR polarization. The rmses in LL on MK were similar with higher values. The actual peak rms at MK exceeds 14 in SPW 3!

Figure 7: J1538-1510 image after multiple self-calibration steps with CALIB.

Table 9: SNRMS output for TY table from BM486A 90cm with no editing.

However, the final FRING step failed more or less completely on the phase calibrator and target source. Both sources were clearly detected well on short spacings and, especially the target, were not detected on long spacings. The phase calibrator was SPLIT without the final FRING and was self-calibrated with CALIB. That model was then used to run CALIB, phase only, on the main uv data set with only $5 \%$ failures. This calibration was then applied to the target source. After a SPLIT, the target source was self-calibrated. Its total Clean flux density started at 127 mJy , rose to 830 mJy with phase-only self-cal, but then dropped a lot with amplitude and phase self-cal even with gain normalization turned on. The final image contained only 119 mJy but with a very low rms $0.046 \mathrm{mJy} / \mathrm{beam}$. The image rms before 'A\& P ' was about $7 \mathrm{mJy} / \mathrm{beam}$. The image shows an extended double source (see Figure 8), but its amplitude is clearly not to be believed.
Self-cal on 3C273 started and ended with Cleaned flux density 8.6 Jy with the image rms dropping from 173 mJy /beam to 43 mJy /beam. Phase-only self-cal did raise the Cleaned flux density to 9.88 Jy but this is still rather less than found in the previous two data sets. J1258-2219 started with a Clean flux density of 395 mJy which increased slightly with phase-only self-cal and then dropped to 295 mJy with A\& P. The image rms started at $6.2 \mathrm{mJy} /$ beam and dropped to $2.1 \mathrm{mJy} /$ beam.

Figure 8: Contour plot of final J1314-2029 image.

## 8 Conclusion

Unlike S-band, the 50 cm and 90 cm data from the VLBA appear to be usable with caution. The total bandwidth is small, limiting the sensitivity. Three science experiments were examined and one of the three failed to detect the phase calibrator and target sources while the second had quite reasonable results including a usable image of the target source at 90 cm (but not at 50 cm ). The third data set produced, with some difficulty, reasonable images of all 3 sources observed although the amplitude of the images is not well calibrated. The DQ runs examined detected each source observed quite well. It is clear that RFI is a problem at these wavelengths, but judicious editing of the data when the Tsys values are unreasonable should eliminate the data affected. RFI spikes due to pulse cals and to external sources are seen in the autocorrelation spectra but do not seem to cause spectral effects in the cross-correlation data except when the data are rendered unusable. Amplitude calibration particularly at 50 cm may be affected by unflagged RFI and poor calibration of the noise tubes. The source of the poor and variable amplitude calibration of BM468 is not known.
