1 INTRODUCTION

This document summarizes the current observational capabilities of NRAO's Very Long Baseline Array (VLBA). The VLBA is an array of 10 25-m diameter antennas distributed over United States territory (Kellermann & Thompson 1985; Napier *et al.* 1994). It is the first astronomical array dedicated to observing by the method of Very Long Baseline Interferometry (VLBI), pioneered in the 1960s. The VLBA offers (1) in absentia, year-round antenna and correlator operation; (2) antenna locations selected to optimize u - v plane coverage; (3) 9 receivers in the range 90 cm to 7 mm at each antenna; (4) quick computer control of receiver selection (receiver agility) and of frequency selection for a given receiver (frequency agility); and (5) smooth integration of data flow from the acquisition to the processing to the post-processing stages. VLBA observations conducted in VLBA (Romney 1990) and Mark III (Rogers *et al.* 1983) data formats can acquire simultaneous dual circular polarizations from any single receiver or from the 13/4 cm receiver pair.

This document's primary intent is to provide in concise form the minimal information needed to formulate technically sound proposals for observing time on VLBA antennas. Its secondary aim is to provide resource lists of relevant software and documentation, plus key NRAO personnel who can be consulted for further, more detailed information. This document will be updated regularly, with updates being paper mailed to everyone on the VLA/VLBA master address list. If you want a paper copy of this document, then request one from Rita Salazar (see Section 25.4); she will also add you to the master list so you will automatically receive printed updates. This document is also available via either anonymous-guest FTP as a \LaTeX PostScript file with name "obssum.vlba.ps" in directory "pub" on host "ftp.aoc.nrao.edu" (146.88.1.4) or via the Mosaic on-line information system (see Section 25.3). When this document is updated, abstracts of any major changes will be announced via the NRAO VLBI e-mail exploder and the NRAO Newsletter. Anyone wanting to be added to this exploder should send an appropriate mail message to "vlbi-request@nrao.edu".

Where possible, the symbols used in this document are the same as those in *Synthesis Imaging in Radio Astronomy*, 1989, edited by R.A. Perley, F.R. Schwab, & A.H. Bridle, published as Volume 6 of the Astronomical Society of the Pacific Conference Series. However, the present document introduces some new symbols as well.

The VLBA is operated remotely from the Array Operations Center

(AOC) in Socorro, New Mexico, with local assistance at each VLBA antenna site provided by site technicians.

2 ANTENNA SITES

Table 1 gives the surveyed geographic locations of the 10 antennas comprising the VLBA (Wade 1989), plus the 2 character codes used to identify the antennas. The antennas are ordered East through West. The SC location refers to the Puerto Rican Datum of 1949. The MK location refers to the Old Hawaiian Datum of 1866. All other locations refer to the North American Datum of 1927.

Table 1: Geographic Locations and Codes

Location	North Latitude [° ' "]	West Longitude [° ' "]	Elevation [m]	Code

3 ANTENNAS

The main reflector of each VLBA antenna is a 25-m diameter dish which is a shaped figure of revolution with a focal-length-to-diameter ratio of 0.354. A 3.5-m diameter Cassegrain subreflector with a shaped asymmetric figure is used at all frequencies above 1 GHz, while the prime focus is used at lower frequencies. The antenna features a wheel-and-track mount, with an advanced-design reflector support structure. Elevation motion occurs at a rate of 30 degrees per minute between a hardware limit of 2 degrees and a

software limit of 90 degrees. This software limit will eventually be lifted, allowing over-the-top elevation motion to 125 degrees. Azimuth motion has a rate of 90 degrees per minute between limits of -90 to 450 degrees. Antennas will be stowed to avoid operation in high winds. Snow or ice accumulation will also be avoided.

4 FREQUENCIES

Table 2 gives the frequency ranges for the 9 receiver/feed combinations now available on all 10 VLBA antennas. Ranges as measured by Biretta (1991) are given where available; *these correspond to the frequencies at which the zenith system equivalent flux densities (SEFD) in Jy increase by a factor of 1.4*, and although they are based on only a few antennas at each wavelength, the similarity among the antennas suggests that the results apply to the entire VLBA. Frequency ranges based on nominal design specifications, rather than measurements at the antennas, are indicated.

Also appearing in Table 2 are parameters characterizing the performance of a typical VLBA antenna for the various receiver/feed combinations. Columns [3] and [4], respectively, give typical VLBA zenith *SEFDs* and typical VLBA zenith opacity-corrected gains in K Jy^{-1} . These were obtained by averaging right circularly polarized (RCP) and left circularly polarized (LCP) values from 7-10 antennas at 90-1 cm (Walker 1992, plus updates) and from 8 antennas at 7 mm (Dhawan & Zensus 1994). The typical zenith *SEFDs* can be used to estimate root-mean-square (RMS) noise levels on a baseline between 2 VLBA antennas (ΔS for a *single polarization*; see Equation 2) and in a VLBA image (ΔI_{m} for a *single polarization*; see Equation 3). Characteristic values for $\Delta S^{128,2\text{m}}$ assuming a fringe-fit interval of $\tau_{\text{ff}} = 2$ minutes and for $\Delta I_{\text{m}}^{128,8\text{h}}$ assuming a total integration time on source of $t_{\text{int}} = 8$ hours also appear in Table 2; both of these characteristic values assume an aggregate recording bit rate equal to the “sustainable” limit of 128 Mbits per second (Mbps) (see Section 5.16). No $\Delta S^{128,2\text{m}}$ or $\Delta I_{\text{m}}^{128,8\text{h}}$ entries are given for 90 and 50 cm because adequately wide bandwidths cannot be obtained. Entries for 7 mm are also not given, since a 2-minute fringe-fit interval is unrealistically long.

PT has an additional receiver at 3 cm, with zenith *SEFDs* of 715 Jy and 561 Jy for RCP and LCP, respectively; and zenith gains of 0.130 K Jy^{-1} and 0.166 K Jy^{-1} for RCP and LCP, respectively. The frequency range of this receiver is 10.2-11.2 GHz, based on the design specifications.

Opacity-corrected zenith gains are needed for current continuum amplitude calibration techniques. These zenith gains vary from antenna to antenna, and will be monitored by VLBA operations and communicated to users (see Section 14). The typical values appearing in Table 2 are meant to be illustrative only.

Table 2: Frequency Ranges and Typical Performance Parameters

Receivers and Feeds	Frequency Range [GHz]	Typical Zenith <i>SEFD</i> [Jy]	Typical Zenith Gain [K Jy ⁻¹]	$\Delta S^{128,2m}$ [mJy]	$\Delta I_m^{128,8h}$ [μ Jy beam ⁻¹]
90 cm	0.312 - 0.345 ^(a)	2075	0.107
50 cm	0.600 - 0.630 ^(b)	2191	0.086
20 cm	1.30 - 1.70 ^(c)	298	0.100	4.8	46
13 cm	2.13 - 2.35	332	0.092	5.3	51
13 cm ^(d)	2.13 - 2.35	420	0.076	6.8	65
6 cm	4.50 - 5.14	296	0.129	4.8	46
4 cm	7.88 - 8.93	314	0.116	5.1	49
4 cm ^(d)	7.88 - 8.93	398	0.110	6.4	62
2 cm	12.0 - 15.4 ^(e)	510	0.111	8.2	79
1 cm	21.1 - 24.6	930	0.092	15	144
7 mm	42.3 - 43.5 ^(e)	1851	0.064

Notes:

(a) Entire range not usable due to narrow band radio frequency interference (RFI); see Biretta (1991).

(b) Entire range not usable due to television interference; see Biretta (1991). A filter passing 609-613 MHz is routinely used at all antennas. Although this filter can be removed, its removal is *not* recommended.

(c) UPPER LIMIT: Biretta's upper limit of 1.70 GHz was measured using a bandwidth of 16 MHz, indicating that broad band observations above that frequency will be problematic. The design specification upper limit is 1.75 GHz to accommodate the 1.72 GHz OH line. The 20 cm receiver/feed should permit narrow band (e.g., OH line) work at 1.72 GHz, but the success of such observations will depend upon the RFI environment. LOWER LIMIT: FD and KP have additional filters to limit local radar RFI below 1350 MHz. The local radar RFI at SC is so extreme that SC's IF converter output is filtered to pass only 700 to 1000 MHz; consequently, multi-frequency synthesis observations involving SC require two front end synthesizer settings to span the 20 cm band and so *cannot* be done simultaneously.

(d) With 13/4 cm dichroic.

(e) Design specification.

As indicated in the footnotes to Table 2, RFI is known to be a problem

at all VLBA sites at 90 cm and 50 cm. RFI is also problematic at some sites at some times within the 20 cm and 13 cm regions. The AOC frequency coordinator, Bill Brundage (see Section 25.4), can be consulted for details.

5 VLBA SIGNAL PATH

This section describes the devices in the signal path at a VLBA antenna site. Devices in Sections 5.1-5.6 and 5.8-5.11 are located at the antenna; all others are in the site control building.

5.1 Antenna and Subreflector

These concentrate the radio frequency (RF) radiation. Antenna pointing and subreflector position are controlled by commands from the site computer based on the current observing schedule and/or provided by the AOC operators or by the site technicians.

5.2 Feed

The feed collects the RF radiation. All feeds and receivers are available at any time, and are selected by subreflector motion controlled by the computer.

5.3 Polarizer

This device converts circular polarizations to linear for subsequent transmission. For receivers above 1 GHz, the polarizer is at cryogenic temperatures.

5.4 Pulse Cal

This system injects calibration tones based on a string of pulses at intervals of 1.0 or 0.2 microseconds. See Section 15.2 for more details.

5.5 Noise Cal

This device injects switched, well calibrated, broadband noise for system temperature measurements. Synchronous detection occurs in the intermediate frequency (IF) distributors (see Section 5.12) and base band converters (see Section 5.13). Switching is done at 80 Hz.

5.6 Receiver

The receiver amplifies the signal. Most VLBA receivers are HFETs at a physical temperature of 15 K, but the 90 cm and 50 cm receivers are GAS-FETs at room temperature. Each receiver has 2 channels, one for RCP and one for LCP. The 1 cm and 7 mm receivers also perform the first frequency down conversion.

5.7 Maser

The maser is a very stable frequency standard with two output signals, one at 100 MHz and one at 5 MHz. The 100 MHz output is the reference for the front end synthesizers (see Section 5.9) and the pulse cal system (see Section 5.4 and Section 15.2). The 5 MHz output is the reference for the base band converters (see Section 5.13), the formatter (see Section 5.15), and the antenna timing.

5.8 Local Oscillator Transmitter and Receiver

The local oscillator (LO) transmitter and receiver multiplies the 100 MHz from the maser to 500 MHz and sends it to the antenna vertex room. A round trip phase measuring scheme monitors the length of the cable used to transmit the signal so that phase corrections can be made for temperature and pointing induced variations.

5.9 Front End Synthesizer

The front end synthesizer generates the reference signals used to convert the receiver output from RF to IF. The lock points are at $(n \times 500) \pm 100$ MHz, where n is an integer. The synthesizer output frequency is between 2.1 and 15.9 GHz. There are 3 such synthesizers, each of which is locked to the maser. One synthesizer is used for most wavelengths, but two are used at 1 cm, at 7 mm, and for the wide band mode at 4 cm described in Section 5.10.

5.10 IF Converter

The IF converter mixes the receiver output signals with the first LO generated by a front end synthesizer. Two signals between 500 and 1000 MHz are output by each IF converter, one for RCP and one for LCP. The same LO

signal is used for mixing with both polarizations in most cases. However, the 4 cm IF converter has a special mode that allows both output signals to be connected to the RCP output of the receiver and to use separate LO signals, thereby allowing the use of spanned bandwidths exceeding 500 MHz. Also, the 90 cm and 50 cm signals are combined and transmitted on the same IFs. The 50 cm signals are not frequency converted, while the 90 cm signals are upconverted to 827 MHz before output.

5.11 IF Cables

There are four of these, labeled A, B, C, and D. Each IF converter normally sends its output signals to A and C, or else to B and D, although switching is available for other possibilities if needed. By convention, the RCP signals are sent to A or B while the LCP signals are sent to C or D. Normally only 2 cables will be in use at a time. Certain dual frequency modes, especially 13 cm and 4 cm, can use all four cables.

5.12 IF Distributers

The IF distributers make 8 copies of each IF, one for each base band converter (see Section 5.13). They also can optionally switch in 20 db of attenuation for solar observations. There are two IF distributers, each handling two IFs. Power detectors allow the determination of total and switched power in the full IF bandwidth for system temperature determinations and for power level setting.

5.13 Base Band Converters

The base band converters (BBCs) mix the IF signals to base band and provide the final analog filtering. Each of 8 BBCs generates a reference signal between 500 and 1000 MHz at any multiple of 10 kHz. Each BBC can select as input any of the four IFs. Each BBC provides the upper and lower sidebands as separate outputs, allowing for a total of 16 "BB channels", where one BB channel is one sideband from one BBC. Allowed bandwidths per BBC are 0.0625, 0.125, 0.25, 0.5, 1, 2, 4, 8, and 16 MHz. Thus the 16 possible BB channels can cover an aggregate bandwidth up to 256 MHz. The BBC signals are adjusted in amplitude. With automatic leveling turned on, the power in the signals sent to the samplers is kept nearly constant, which is important for the 2-bit (4-level) sampling mode (see Section 5.14).

The BBCs contain synchronous detectors that measure both total power and switched power in each sideband for system temperature determination.

5.14 Samplers

Samplers convert the analog BBC outputs to digital form. There are two samplers, each of which handles signals from 4 BBCs. Either 1-bit (2-level) or 2-bit (4-level) sampling may be selected. A single sample rate applies to all BB channels; rates available are 32, 16, 8, 4, 2, 1, or 0.5 Msamples per second on each channel.

5.15 Formatter

The formatter selects the desired bit streams from the samplers, adds timing and other information, fans the bit streams in or out (combines several slow input signals onto one tape track or spreads one fast input signal over several tape tracks), establishes the barrel roll scheme used to rotate the bit stream/track mapping with time, and sends the output signals to the tape recorders. As many as 32 bit streams can be formatted, with a bit-stream:track multiplexing scheme of 4:1, 2:1, 1:1, 1:2, or 1:4, which allows for very flexible input signal to output tape track switching. VLBA and Mark III data formats are supported. Up to 16 pulse cal tones will be detectable simultaneously, but this is not yet fully implemented. Up to 4 Mbits can be captured and sent to the site computer and on to the AOC for various tests, including real time fringe checks.

5.16 Tape Recorders

These are high speed longitudinal instrumentation tape recorders that use 1 inch wide tape on reels 14 inches in diameter. The headstack contains 36 heads, 32 for data and 4 for system information, cross-track parity, or duplicate data (if, for example, a head dies). The headstack can be moved under site computer control transverse to the tape motion. The heads are much narrower than the spacing between heads, so multiple pass recording can be used with 14 passes, or more if not all heads are used in each pass.

As many as 32 data tracks can be written to 1 tape drive, with a record rate per track of 8, 4, or 2 Mbps. This can result in an aggregate bit rate of as much as 256 Mbps for 1 tape drive. A doubling of this aggregate bit rate will be possible once appropriate software is available. However, operational constraints require that a "sustainable" limit of 128 Mbps (averaged over 24

hours) be imposed on the aggregate bit rate. This can be achieved either by recording at 128 Mbps or by arranging that the duty cycle (ratio of recording time to total allocated time) be less than unity. Rare, particularly meritorious projects may request exemption from the sustainable bit rate limit.

5.17 Site Computer

A VME site computer running VxWorks controls all site equipment based on commands in the current observing schedule or provided by the AOC operators or by the site technicians. All systems are set as requested in the current schedule for each new observation.

5.18 Monitor and Control Bus

This carries commands from the site computer to all site hardware and returns data from the site hardware to the computer.

5.19 Mark II System

The Mark II (Clark 1973) formatter accepts data from a sideband of BBC number 1 plus the 5 MHz signal from the maser, keeps time, samples the data, formats it for recording, and sends it at 4 Mbps to modified home video cassette recorders (VCRs). An interface to the site computer allows the formatter status to be checked and the input BBC sideband to be selected. The interface also has a data quality analyzer to allow playback checks of the VHS tapes loaded in the VCRs. A VHS tape can hold 4 hours of data. A Mark II system includes 4 or 5 VCRs, to allow Mark II recording with infrequent tape changes. Mark II systems are available at all VLBA antennas except KP, LA, and FD.

5.20 GPS Receiver

This device acquires time from the Global Positioning System (GPS). GPS time is usually used to monitor the site clock. GPS time is occasionally used to set the site clock if it is disrupted for some reason.

6 RECORDING FORMATS

The VLBA can record data in VLBA, Mark III, and Mark II formats. Characteristics of observations recorded in VLBA format are described in Section 5 and elsewhere in this document. Mark III observations are limited to that format's 4-MHz maximum BB channel bandwidth and 1-bit sampling, and to the VLBA's 8-BBC complement.

Single-channel Mark II recording is supported at all VLBA antennas except KP, LA, and FD; simultaneous dual-polarization observations obviously cannot be made in this mode. Mark II recording capability will continue to be supported by the VLBA until 1995 January.

The VLBA cannot record in the Japanese K4 format or the Canadian S2 format.

7 CORRELATORS

7.1 VLBA

The VLBA correlator accommodates the full range of scientific investigations for which the Array was designed. It supports wideband continuum, high-resolution spectroscopy, bandwidth synthesis, and polarimetric observations, as well as more specialized techniques such as simultaneous multiple frequencies or phase centers, frequency or phase-center switching, and pulsar gating.

The correlator is designed to process all observations involving VLBA stations. With its 20-station capacity and extensive sub-arraying capabilities, it can correlate an extended array combining the VLBA with as many as 10 foreign stations, or an extreme-wideband VLBA observation using both recorders at each of 10 stations, or two 10-station intra-VLBA observations, or virtually any combination of smaller sub-arrays, each in a single processing pass.

Each station input comprises 8 parallel "channels" (as defined in Section 5.13), which operate at a fixed rate of 32 Msamples per second, for either 1- or 2-bit samples. Observations at lower sample rates generally can be processed with a speed-up factor of 2 (for 16 Msamples per second) or 4 (for 8 Msamples per second or less) relative to observe time. Special modes are invoked automatically to enhance sensitivity when fewer than 8 channels are observed, or when correlating narrowband or oversampled data. The correlator accepts input data recorded in either VLBA or Mark III longitudinal

format, but not in Mark II format.

Each input channel can be resolved into 1024, 512, 256, 128, 64, or 32 “spectral points”, subject to a limit of 2048 points per baseline across all channels. Adjacent, oppositely polarized channels can be paired to produce all four Stokes parameters; in this case the 2048-point limit implies the maximum spectral resolution is 128 points per polarization state. The user may also specify a spectral smoothing function, or request an “interpolated” spectrum suitable for inversion to a cross-correlation function if further work is required in that domain.

The correlator forms cross-spectral power measurements on all relevant baselines in a given sub-array, including individual antenna “self-spectra”. These can be integrated over any integral multiple of the basic integration cycle, 131.072 milliseconds (2^{17} microsec). Adjacent spectral points may be averaged while integrating to reduce spectral resolution. A time-domain transversal filter is available at the output from the integrator to maximize the fringe-rate window while further reducing the data rate.

Correlator output is written in a “FITS Binary Table” format, and will eventually include amplitude and pulse calibration data obtained at observe time, and editing flags from both observing stations and the correlator. All results are archived on digital-audio-tape (DAT) cassettes. The output data rate is limited administratively to 0.5 Mbytes per second, which must be shared among all simultaneous correlator sub-arrays. Data are copied from the archive for distribution to users on a variety of media, with DAT and Exabyte currently given primary support.

Operation of the correlator is governed primarily by information in the form either of station logs generated from the VLBA array control system’s monitor data or log information from foreign stations. A few additional items (all of which have been mentioned above) are specified by the user as part of the observation schedule via the VLBA OBSERVE program, although it is possible to modify these inputs prior to correlation if necessary. Supervision of the correlation process is the responsibility of VLBA operations personnel; user participation during correlation is not expected (nor easily arranged, as explained below).

Scheduling of the correlator is currently done on a very short time-scale of days to optimize use of the correlator’s resources and the Array’s stock of tapes. This makes it impractical, in general, to schedule visits by users during correlation of their data. As described in Section 22, however, users are encouraged to visit the AOC after correlation for post-processing analysis.

7.2 Mark II

The Mark II format is currently supported on only 7 VLBA antennas. This support will end in 1995 January. Continuum projects can be processed on the 16-station Caltech/JPL Mark II correlator operated by Caltech in Pasadena, California but prior arrangement for access to correlation facilities must be obtained separately (contact: S.C. Unwin, Astronomy Department 105-24, Caltech, Pasadena, California 91125, USA).

8 ANGULAR RESOLUTION

Table 3 gives the maximum lengths rounded to the nearest km (B_{\max}^{km}) for each of the VLBA's 45 internal baselines. Both the upper left and lower right portions of the table are filled to make it easier to use. A measure of the corresponding resolution (θ_{HPBW}) in milliarcseconds (mas) is

$$\theta_{\text{HPBW}} \sim 2063 \times \frac{\lambda^{\text{cm}}}{B_{\max}^{\text{km}}} \text{ mas}, \quad (1)$$

where λ^{cm} is the receiver wavelength in cm. A uniformly weighted image made from a long u - v plane track will have a synthesized beam with a slightly narrower minor axis FWHM. For the longest VLBA baseline, θ_{HPBW} ranges from 20 to 0.2 mas as the wavelength runs from 90 cm to 7 mm.

Table 3: Maximum VLBA Baseline Lengths in km (B_{\max}^{km})

9 *u-v* PLANE COVERAGE

Plots of the *u-v* plane coverage with the VLBA for sources at declinations of $+64^\circ$, $+30^\circ$, $+06^\circ$, and -18° are shown in Figure 1 for horizon-to-horizon tracks and in Figure 2 for single “snapshot” tracks of duration $\frac{1}{2}$ hour approximately when the source transits New Mexico. Similar plots can currently be generated by program PC-SCHED distributed by Haystack Observatory; Section 25.1 describes how to obtain this program. *u-v* plots can also be calculated with program HAZI distributed with the Caltech VLBI Analysis Programs. See Section 25.1 for instructions on how to obtain this software. Both PC-SCHED and HAZI require coordinates for VLBA antennas. An NRAO VLBA OBSERVE program is currently under development (see Section 19). Among its various project planning tools will be the ability to produce *u-v* plots.

10 TIME RESOLUTION

Time resolution is set by the VLBI correlator accumulation time. At the VLBA correlator it will be 1 or 2 seconds for most projects, although a minimum accumulation time of 131 milliseconds will be available for special projects. Pulsar gating is planned for the VLBA correlator but implementation is not expected until 1995.

11 SPECTRAL RESOLUTION

Spectral resolution is set by the VLBI correlator. With the VLBA correlator each BB channel can be divided into 32, 64, 128, 256, 512, or 1024 spectral points, subject to the limitations specified in Section 7.1. The spectral resolution is the bandwidth per BB channel divided by the number of spectral points. The VLBA correlator can apply an arbitrary special smoothing, which will affect the statistical independence of these points and thus the effective spectral resolution.

12 BASELINE SENSITIVITY

Adequate baseline sensitivity is necessary for VLBI fringe fitting, discussed in Section 15.3. The following formula can be used in conjunction with the typical zenith *SEFDs* for VLBA antennas given in Table 2 to calculate the

Figure 1: VLBA u - v plane coverage at four declinations. Horizon-to-horizon tracks for an elevation limit of 10° . Plotted range is ± 9000 km.

RMS thermal noise (ΔS) in the visibility amplitude of a *single polarization* baseline between two identical antennas (Walker 1989b; Crane & Napier 1989):

$$\Delta S = \frac{1}{\eta_s} \times \frac{SEFD}{\sqrt{2 \times \Delta \nu \times \tau_{\text{ff}}}} \text{ Jy.} \quad (2)$$

In Equation 2, $\eta_s \leq 1$ accounts for the VLBI system inefficiency (e.g., quantization in the data recording and correlator approximations). Assume $\frac{1}{\eta_s} \sim 2$

Figure 2: VLBA u - v plane coverage at four declinations. Single “snapshot” tracks at New Mexico transit. Plotted range is ± 9000 km.

for Mark II and III data; values are still to be determined for the VLBA. $\Delta\nu$ is the bandwidth [Hz]; use the full recorded bandwidth for a continuum target and use a spectral channel for a line target. τ_{ff} is the fringe-fit interval [s], which should be less than or about equal to the coherence time τ_{atm} . Equation 2 holds in the weak source limit and assumes 1-bit (2-level) quantization. About the same noise can be obtained with 2-bit (4-level) quantization and half the bandwidth, which gives the same bit rate. The

following very rough coherence times can be expected (Moran 1989a): $\tau_{\text{atm}} \sim 1600$ s at 1 GHz, 160 s at 10 GHz and 16 s at 100 GHz. The actual coherence time appropriate for a given VLBA project can be estimated using observed fringe amplitude data on an appropriately strong and compact source.

13 IMAGE SENSITIVITY

The following formula can be used in conjunction with the typical zenith *SEFDs* for VLBA antennas given in Table 2 to calculate the RMS thermal noise (ΔI_m) expected in a *single-polarization* image, assuming natural weighting (Walker 1989b; Crane & Napier 1989):

$$\Delta I_m = \frac{1}{\eta_s} \times \frac{SEFD}{\sqrt{N \times (N-1) \times \Delta\nu \times t_{\text{int}}}} \text{ Jy beam}^{-1}, \quad (3)$$

where η_s is discussed in Section 12; N is the number of VLBA antennas available; $\Delta\nu$ is the bandwidth [Hz]; and t_{int} is the total integration time on source [s]. Equation 3 also assumes 1-bit (2-level) quantization. If simultaneous dual polarization data are available with the above ΔI_m per polarization, then then for an image of Stokes I , Q , U , or V ,

$$\Delta I = \Delta Q = \Delta U = \Delta V = \frac{\Delta I_m}{\sqrt{2}}. \quad (4)$$

For a polarized intensity image of $P = \sqrt{Q^2 + U^2}$,

$$\Delta P = 0.655 \times \Delta Q = 0.655 \times \Delta U. \quad (5)$$

It is sometimes useful to express ΔI_m in terms of an RMS brightness temperature in Kelvins (ΔT_b) measured within the synthesized beam. An approximate formula for a *single-polarization* image is

$$\Delta T_b \sim 320 \times \Delta I_m \times (B_{\text{max}}^{\text{km}})^2 \text{ K}, \quad (6)$$

where $B_{\text{max}}^{\text{km}}$ is as in Equation 1. The numerical coefficient in Equation 6 differs slightly from that given by Fanti (1989), who assumes a beam area equal to the square of Equation 1; Equation 6 assumes a Gaussian beam area, which is 1.13 times the square of Equation 1.

14 AMPLITUDE CALIBRATION

Traditional calibration of VLBI fringe amplitudes for continuum sources requires knowing the on-source system temperature in Jy (*SEFD*; Cohen *et al.* 1975; Walker 1989a). System temperatures in degrees K (T_{sys}) are measured “frequently” in each BB channel during observations with VLBA antennas; “frequent” means at least once per observation or once every 2 minutes, whichever is shortest. These T_{sys} values are currently delivered to VLBA users in machine readable files that can be read by fringe amplitude calibration programs such as *ANCAL* in the NRAO Astronomical Image Processing System (AIPS) or *CAL* in the Caltech VLBI Analysis Programs. The parameters and file style expected by these programs are documented in their respective help files. Such programs can be used to convert from T_{sys} to *SEFD* by dividing by the VLBA antenna zenith gains in K Jy^{-1} provided by VLBA operations, based upon regular monitoring of all receiver and feed combinations. Anonymous-guest ftp can be used to access these VLBA zenith gains; consult file “vlba_gains.key” in directory “pub” on host “ftp.aoc.nrao.edu” (146.88.1.4). For projects processed on the VLBA correlator, such amplitude calibration data will eventually be delivered directly as tables in the FITS files archived and distributed by NRAO. Single-antenna spectra can be used to do amplitude calibration of spectral line VLBI projects (see Section 17).

Post-observing amplitude adjustments might be necessary for an antenna’s position dependent gain (the “gain curve”) and for the atmospheric opacity above an antenna. A scheme for doing opacity adjustments is described by Leppänen (1993). The VLBA antenna gain curves are provided in the file “vlba_gains.key” described above.

Although experience with VLBA calibration shows that it probably yields fringe amplitudes accurate to 5 percent or less, it is recommended that users observe a few amplitude calibration check sources during their VLBA project. Table 4 gives a suggested list of such sources, selected because they are *likely* to be point-like on inner VLBA baselines at wavelengths of 6 cm and 4 cm. Other sources will be added in the future. VLBA observations of sources in Table 4 can be used (1) to assess the relative gains of VLBA antennas; (2) to test for non-closing amplitude and phase errors; and (3) to check the correlation coefficient scaling factor (traditionally called the b-factor), provided simultaneous source flux densities are available independent of the VLBA observations.

Table 4: Suggested Amplitude Check Sources at 6 cm and 4 cm

15 PHASE CALIBRATION AND IMAGING

15.1 Fringe Finders

VLBI fringe phases are much more difficult to deal with than fringe amplitudes. If the *a priori* correlator model assumed for VLBI correlation is particularly poor, then the fringe phase can wind so rapidly in both time (the fringe rate) and in frequency (the delay) that no fringes will be found within the finite fringe rate and delay windows examined during correlation. Reasons for a poor *a priori* correlator model include source position and antenna location errors, atmospheric (tropospheric and ionospheric) propagation effects, and the behavior of the independent clocks at each antenna. Users observing sources with poorly known positions should plan to refine the positions first on another instrument such as the VLA. To allow accurate location of any previously unknown antennas and to allow NRAO staff to conduct periodic monitoring of clock drifts, each user should include at least one, and preferably two, “fringe finder” sources which are strong, compact, and have accurately known positions. The 6 sources listed in Table 5 are commonly used as fringe finders at centimeter wavelengths. (Warning: some

of these may be unsuitable at some wavelengths on some VLBA baselines; we are still gaining experience using them.) Their positions, accurate to ~ 1 mas, are from Ma *et al.* (1990).

15.2 The Pulse Cal System

VLBA observers using more than 1 BBC will want to sum over the BBCs to reduce noise levels. This should not be done with the raw signals delivered by the BBCs: the independent local oscillators in each BBC introduce an unknown phase offset from one BBC to the next, so such a summation of the raw signals would be incoherent. A so-called “phase cal” or “pulse cal” system (Rogers *et al.* 1983, Alef 1989a) is available at VLBA antennas to overcome this problem. This system, in conjunction with the LO cable length measuring system, is also used to measure changes in the delays through the cables and electronics which must be removed for accurate geodetic and astrometric observations. The pulse cal system consists of a pulse generator and a sine-wave detector. The pulses can be either 0.2 or 1 microsecond in duration. They are injected into the signal path at the 13 cm and 4 cm receivers and serve to define the delay reference point for astrometry. The weak pulses appear in the spectrum as a “comb” of very narrow, weak spectral lines at intervals of 1 MHz (or, optionally, 5 MHz in the new system). The detector measures the phase of one or more of these lines, and their relative offsets can be used to correct the phases of data from different BBCs. The detector is in the correlator for the Mark III system but will be at the antenna in the VLBA. When fully implemented, the pulse cal data will be logged as a function of time during observations with VLBA

antennas, and included in the calibration information delivered to the user in tabular form. AIPS software will then be used to apply the pulse cal data. The implementation date is late 1994. Prior to the availability of the pulse cal information, VLBA users should observe a strong compact source so they can do a “manual” pulse cal (see Section 15.1).

15.3 Fringe Fitting

After correlation, the phases on a VLBA target source can still exhibit high residual fringe rates and delays. Before imaging, these residuals should be removed to permit data averaging in time and - for a continuum source - in frequency. The process of finding these residuals is referred to as fringe fitting. Before fringe fitting, it is recommended to edit the data based on the *a priori* edit information provided for VLBA antennas (see Section 20) that can be passed easily to task UVFLG in AIPS. The old baseline-based fringe search methods have been replaced by more powerful global fringe search techniques (Schwab & Cotton 1983; Alef & Porcas 1986). Global fringe fitting is simply a generalization of the phase self-calibration technique (see Section 15.5), as during a global fringe fit the difference between model phases and measured phases are minimized by solving for the antenna-based instrumental phase, its time slope (the fringe rate) and its frequency slope (the delay) for each antenna (Walker 1989a, c). Global fringe fitting in AIPS is done with program FRING. If the VLBA target source is a spectral line source (see Section 17) or is too weak to fringe fit on itself, then residual fringe rates and delays can be found on an adjacent strong continuum source and applied to the VLBA target source.

15.4 Editing

After fringe-fitting and averaging, VLBA visibility amplitudes should be inspected and obviously discrepant points removed (Walker 1989a). Usually such editing is done interactively using task IBLED in AIPS or program difmap (Shepherd, 1994) in the Caltech VLBI Analysis Programs.

15.5 Self-Calibration, Imaging, and Deconvolution

Even after global fringe fitting, averaging, and editing, the phases on a VLBA target source can still vary rapidly with time because of inadequate removal of antenna-based instrumental phases. If the VLBA target source is sufficiently strong and if absolute positional information is not needed,

then it is possible to reduce these phase fluctuations by looping through cycles of Fourier transform imaging and deconvolution, combined with phase self-calibration in a time interval shorter than that used for the fringe fit. Fourier transform imaging is straightforward (Sramek & Schwab 1989), and done with tasks UVMAP or MX in AIPS or program difmap in the Caltech VLBI Analysis Programs. The resulting VLBI images are deconvolved to rid them of substantial sidelobes arising from relatively sparse sampling of the u - v plane (Cornwell & Braun 1989; Wilkinson 1989b). Such deconvolution is achieved with programs based on the CLEAN or Maximum Entropy methods in AIPS or difmap in the Caltech VLBI Analysis Programs.

Phase self-calibration just involves minimizing the difference between observed phases and model phases based on a trial image, by solving for antenna-based instrumental phases (Pearson & Readhead 1984; Cornwell & Fomalont 1989; Wilkinson 1989a; Walker 1989c). After removal of these antenna-based phases, the improved visibilities are used to generate an improved set of model phases, usually based on a new deconvolved trial image. This process is iterated several times until the phase variations are substantially reduced. The method is then generalized to allow estimation and removal of complex instrumental antenna gains, leading to further image improvement. Both phase and complex self-calibration are accomplished with the AIPS task CALIB and with program difmap in the Caltech VLBI Analysis Programs. Self-calibration should only be done if the VLBA target source is detected with sufficient signal-to-noise in the self-calibration time interval and if absolute positional information is not needed.

The useful field of view in VLBI images can be limited by finite bandwidth, integration time, and non-coplanar baselines (Cotton 1989b; Bridle & Schwab 1989; Perley 1989a; Fanti 1989). Measures of image correctness - image fidelity and dynamic range - are discussed in the VLA case by Perley (1989b) and in the VLBI case by Wilkinson (1987).

15.6 Phase Referencing

If the VLBA target source is not sufficiently strong for self-calibration and/or if absolute positional information is needed, then VLBA phase referenced observations must be employed (Alef 1989b; Lestrade 1991). A VLBA phase reference source should be observed frequently and be within a few degrees of the VLBA target region, otherwise differential atmospheric (tropospheric and ionospheric) propagation effects (Moran 1989b) will prevent accurate phase transfer. In the short term, VLBA users can draw candidate phase

calibrators from the MERLIN phase calibrator grid of Patnaik *et al.* (1992), which will eventually be extended to cover the sky north of declination -30 degrees. Soon after the VLBA correlator achieves smooth operation, NRAO staff will begin a systematic survey of these MERLIN phase calibrators to determine which ones are compact enough to serve as good VLBA phase reference sources and to obtain improved reference source positions.

16 POLARIMETRY

In VLBA polarimetric observations, BB channels are assigned in pairs to opposite hands of circular polarization at each frequency. Such observation can be recorded in VLBA or Mark III format.

Although straight-forward conceptually, calibration of continuum polarimetry has traditionally been very difficult (Cotton 1989a; Roberts, Brown, & Wardle 1991). Steps that must be followed include normal amplitude calibration; fringe-fitting; self-calibration and Stokes I image formation; instrumental polarization calibration; setting the absolute position angle of electric vectors on the sky; and correction for ionospheric Faraday rotation, if necessary. The polarization calibration path in AIPS is currently being actively developed, tested, and documented (Cotton 1992). It includes powerful global fringe-fitting techniques to locate weak cross-polarized signals (Brown, Roberts, & Wardle 1989).

To permit calibration of the instrumental polarization at centimeter wavelengths, VLBA users should include observations of sources either with simple linearly polarized structure (e.g., 1404+286 = J1407+28 = OQ208, see Table 4) or no linearly polarized emission (e.g., 0316+413 = J0319+41 = 3C84, see Table 5). To set the absolute position angle of electric vectors on the sky, VLBA users will want to observe a source whose linear polarization is known at the epoch of their project. BL Lacertae objects can be used for this purpose (Gabuzda *et al.* 1992), with the caveat that their linearly polarized emission typically varies rapidly in time.

17 SPECTRAL LINE VLBI

Diamond (1989a, b) describes the special problems encountered during data acquisition, correlation, and post-processing of a spectral line VLBI project. The spectral line VLBA user must know the transition rest frequency, the approximate velocity and velocity width for the line target, and the corre-

sponding observing frequency and bandwidth. The schedule should include observations of a strong continuum source to be used for bandpass calibration, as well as scans of a continuum source reasonably close to the line target to be used as a fringe-rate and delay calibrator.

Post-processing steps include performing Doppler corrections for the Earth's rotation and orbital motion (the correction for rotation is not necessary with observations correlated on the VLBA or any other correlator with antenna based fringe rotators); amplitude calibration using single-antenna spectra; fringe fitting the nearby continuum calibrator and applying the results to the line target; referencing phases to a strong spectral feature in the line source itself; and deciding whether to do fringe rate mapping (Walker 1981) or normal synthesis imaging and then form a spectral line cube. All these post-processing steps, except for fringe-rate mapping, can currently be done in AIPS.

18 PROPOSALS

18.1 Preparing a Proposal

After composing the scientific justification and identifying the desired VLBI target source(s), select an appropriate VLBI array. Possibilities include:

1. The VLBA alone (SC, HN, NL, FD, LA, PT, KP, OV, BR, and MK), with the possible inclusion of the VLA. The VLA can be requested in either phased array or single antenna mode; consult Wrobel & Claussen (1994) for information on VLBI at the VLA. Proposal deadlines are February 1, June 1, and October 1. Observing periods for such projects are identical to those for the VLA and are advertised regularly in the NRAO Newsletter. Observing time is allocated by the VLA/VLBA Scheduling Committee. Approved VLBA projects are scheduled by the VLBA scheduler Barry Clark (see Section 25.4).
2. The European VLBI Network (EVN). Prospective proposers can consult Alef, Garrett, & Mantovani (1991; the EVN Handbook hereafter) for updated information on EVN members and the capabilities of EVN antennas. (The EVN Handbook can be obtained through account VLBINFO on ASTBO1. The Internet address is "astbo1.bo.cnr.it" (192.167.165.1). Span access is via ASTBO1::VLBINFO or 38057::VLBINFO.) The EVN handles the proposing, refereeing, and scheduling

mechanisms for such projects, which must all be run during a regular VLBI Network session. EVN proposal deadlines are February 1, June 1, and October 1. VLBI Network session dates and wavelengths are routinely announced by EVN mailings and in the NRAO Newsletter. Observing time is allocated by the EVN Program Committee. Approved EVN projects are scheduled by the EVN scheduler R. Schwartz. Any EVN proposal requesting the VLBA or two or more of the non-EVN VLBA affiliates identified in Item 3 below constitutes a global proposal, and must be submitted to both the VLBA and the EVN.

3. VLBA affiliates in addition to the VLA include Arecibo, Effelsberg, the Deep Space Network, Green Bank, Medicina, and Noto. A VLBA proposal requesting such affiliates is handled as described in Item 1 above, except that if two or more EVN institutes are requested, then it is a global proposal and must be submitted to both the VLBA and the EVN. A VLBA project involving affiliates other than the VLA might be run outside of a regular VLBI Network session, depending on which affiliates are involved. In particular, about 20 days of time per year, outside of regular VLBI Network sessions, has been reserved for joint VLBI projects involving the VLBA and Effelsberg; submit proposals for such joint time both to the NRAO and to the MPIfR.

Once the appropriate VLBI array is selected, run Haystack's PC-SCHED program or Caltech's UPTIME program to determine the Greenwich Sidereal Time range during which the VLBI target source(s) is (are) up at the selected antennas. Haystack's PC-SCHED program or Caltech's HAZI program can be used to evaluate the u - v plane coverage provided by the selected antennas (see Section 9). The NRAO VLBA OBSERVE program, currently under development, will include UPTIME and HAZI-like functions among its project planning tools; see Section 19.

Those proposing observations in VLBA format should consult files
"std_modes.vlba",
"bas_modes.vlba", and
"setup_names.vlba"

in directory "pub" on host "ftp.aoc.nrao.edu" (146.88.1.4) (also available via the Mosaic system (see Section 25.3)) to identify which VLBA setup(s) is (are) desired.

18.2 Submitting a Proposal

All VLBA proposals must be submitted with a VLBI Proposal Cover Sheet, which is available as described in Section 18.3. The cover sheet can be used to request the VLBA and/or VLBA affiliates. If the VLA is requested as an element of the VLBI array, then a separate VLA proposal is not needed. VLBA proposals should be sent to: Director, NRAO, 520 Edgemont Road, Charlottesville, Virginia 22903-2475, USA. All EVN proposals must be submitted with a VLBI Proposal Cover Sheet. EVN proposals should be sent to: R. Schwartz, EVN Scheduler, MPIfR, Auf dem Hügel 69, D-53121 Bonn, GERMANY). Global VLBI observations require proposals to both the VLBA and EVN, using the addresses given above.

Proposals requesting antennas unaffiliated with the VLBA or the EVN must be sent to the directors of those antennas.

18.3 The VLBI Proposal Cover Sheet

A VLBI Proposal Cover Sheet must accompany all VLBA, EVN, and global proposals. Tex or PostScript versions authored by Barry Clark are available via anonymous-guest FTP on host "ftp.cv.nrao.edu" in directory "proposal". If you want to print a PostScript cover sheet at your home institution that will be filled in *after* printing, then get file `covervlbi.ps`. If you want to print a PostScript cover sheet at your home institution that will be filled in *before* printing, then get files `covervlbi.tex`, `nraologo.ps`, and `evnlogo.ps`. Printed cover sheets can be requested from Joanne Nance (`jnance@nrao.edu`, telephone +1-804-296-0323).

19 PREPARATION FOR OBSERVING

Users allocated VLBA observing time will be sent detailed observing schedule preparation instructions. Currently, the preparation of observing schedules for VLBA, Mark III, and Mark II format observations requires running software on AOC computers, with local assistance provided by the VLA/VLBA data analysts and AOC scientific staff. This arrangement ensures that observing schedules contain proper antenna electronics setup information and are fully compatible with current hardware and control software. Mark II and VLBA format projects are scheduled using program `SCHED` in the Caltech VLBI Analysis Programs. Mark III format projects are usually scheduled with Haystack's PC-`SCHED` program; the so-called `DRUDG`

file output by PC-SCHED is translated at the AOC for use by the Caltech program SCHED, which is then used to create the VLBA observing schedules.

Eventually, an NRAO VLBA OBSERVE program will be widely distributed to the VLBA user community, allowing users to make complete and accurate VLBA observing schedules at their home institutions. VLBA OBSERVE is currently being prototyped by Wes Young (see Section 25.4). The base prototype consists of several parts: (1) antenna database; (2) source catalogs; (3) frequency setups catalog; (4) what's up; (5) schedule maker (VLBA, Mark III); (6) VLBA and VLA antenna control file generator; and (7) SNAP file generator. The base prototype will be available only for SparcStations or their clones running Openwindows or X11R5, and should be ready in summer 1994. Users will be welcomed to try out the prototype. Announcements of its availability and how to get it using anonymous-guest FTP will be made on the NRAO VLBI e-mail exploder and in the NRAO Newsletter. After some feedback on the prototype, construction of the official release, involving generic X-windows on many different computers, will commence. A VT100-terminal-based version will follow later.

20 DURING OBSERVING

Each VLBA project is run remotely from the AOC by VLBA operations. No observing assistance by a VLBA user is expected, although VLBA operations should be able to reach the observer by telephone during the project. As the project progresses, the VLBA operator monitors the health and state of the antennas and tape recording systems, mainly using a compact yet comprehensive display program. Remote observers can access this display over Internet by logging in to "vlbacc.aoc.nrao.edu" (146.88.3.2) as user vldis. Various logging, calibration, and flagging data are automatically recorded by the monitor and control system running on the station computer at each VLBA site. If necessary, the VLBA operator can request local assistance from a site technician at each VLBA antenna. Recorded tapes are automatically shipped from each VLBA antenna to the correlator specified by the observer.

21 POST-PROCESSING SOFTWARE

21.1 NRAO AIPS

AIPS is a set of programs for the analysis of continuum and line VLBI observations involving one or more BB channel. These programs are available for a wide range of computer operating systems. See Section 25.1 for instructions on how to obtain this software. Extensive on-line internal documentation can be accessed within AIPS. Chapter 11 in the AIPS Cookbook provides useful “how-to” guidance for those reducing VLBI data. An AIPS Cookbook can be requested from Theresa McBride (see Section 25.4). More extensive documentation addressing VLBI calibration is currently in preparation.

21.2 The Caltech VLBI Analysis Programs

The Caltech VLBI Analysis Programs are a set of programs for the planning and analysis of continuum VLBI observations involving one BB channel. These programs are available for VAX/VMS, Sun UNIX, and Convex UNIX. A summary of the major programs can be found in Bulletin of the American Astronomical Society, volume 23, page 991, 1991. See Section 25.1 for instructions on how to obtain this software, along with its substantial on-line internal documentation.

22 VISITING THE AOC

VLBA users are *strongly* encouraged to make post-processing visits to the AOC. This is especially recommended for users dealing with data processed on the VLBA correlator. The VLBA Correlator is scheduled independently of the array: this means that you cannot assume that the correlated data will be available after any given time. *Please contact the operations staff to determine if the correlated data are available before arranging a visit.*

Standard NRAO travel reimbursement policy applies to VLBA data reduction trips to the AOC. Visitors must contact the AOC travel secretary Eileen Latasa (see Section 25.4) at least one week prior to their visit; this timing is needed to optimize the logistics of visitor accommodation, transportation, workstation use, and AOC staff assistance. Students visiting the AOC for their first VLBI or VLBA post-processing trip must be accompanied by their faculty advisor.

23 DATA ARCHIVE AND DISTRIBUTION

An archive of all output from the VLBA correlator will be maintained at the AOC. The user(s) who proposed the observations will retain a proprietary right to the data for a fixed interval of 18 months following the end of correlation of the last observations requested in the original proposal or a direct extension of that proposal. Thereafter, archived data will be available to any user on request. Indices are planned to facilitate this access to archival data.

Data will be distributed on a medium requested by the user. For the initial distribution to the user proposing the observations, this will occur automatically, soon after correlation is complete, provided a medium has been specified with the observing schedule.

Distributed data will conform to the new FITS binary table standard for interferometry data interchange (Diamond *et al.*, 1994), which is read by AIPS task FITLD.

24 PUBLICATION GUIDELINES

24.1 Acknowledgement to NRAO

Any papers using observational material taken with NRAO instruments (VLBA or otherwise) or papers where a significant portion of the work was done at NRAO, should include the following acknowledgement to NRAO and NSF:

*The National Radio Astronomy Observatory is operated by
Associated Universities, Inc., under cooperative agreement with
the National Science Foundation.*

24.2 Preprints

NRAO requests that you submit four copies of all papers which include observations taken with any NRAO instrument or have NRAO author(s) to Ellen Bouton in the Charlottesville Library. NRAO authors may request that their papers be included in the official NRAO preprint series. Multiple author papers will not be included in the series if they are being distributed by another institution. All preprints for distribution should have a title page that conforms to the window format of the NRAO red preprint covers. Note that preprints will be distributed ONLY when the NRAO author so

requests; inclusion in the series is not automatic. This action will also cause the paper to be included in NRAO's publication lists.

24.3 Reprints

NRAO no longer distributes reprints, but will purchase the minimum number of reprints for NRAO staff members. The NRAO does not want reprints, and will not pay for any reprint costs for papers with no NRAO staff author.

24.4 Page Charge Support

The following summarizes NRAO's policy:

- When requested, NRAO will pay the larger of the following:
 - 50% of the page charges reporting original results made with NRAO instrument(s) when at least one author is at a U.S. scientific or educational institution.
 - 100% of the page charges prorated by the fraction of authors who are NRAO staff members.
- Page charge support is provided for publication of color plates.
- To receive page charge support, authors must comply with all of the following requirements:
 - Include the NRAO footnote in the text: "Operated by Associated Universities, Inc., under cooperative agreement with the National Science Foundation."
 - Send four copies of the paper prior to publication to Ellen Bouton in Charlottesville.
 - Notify Ellen Bouton in Charlottesville of the proposed date of publication and apportionment of page charges so that the necessary purchase orders may be initiated. Convenient ways to do this are to send her copies of the completed page charge form, or send her an e-mail message (library@nrao.edu), or call her by telephone at (804)-296-0254.

When filling out page charge forms, use the following information:

- Contact person for NRAO is Ellen Bouton, 804-296-0254.

- Billing address for both page charges and reprints is NRAO Fiscal Division at the Charlottesville address.
- Shipping address for reprints should be the NRAO author.
- On ApJ and AJ forms, cite the purchase order number as “NRAO blanket PO”. For all other publications, call Ellen Bouton for a purchase order number.

25 RESOURCE LISTS

25.1 Software

The following programs or software packages will be of interest to VLBA users, for planning observations and/or for post-processing VLBA data:

1. Caltech VLBI Analysis Programs: Contact T.J. Pearson, Astronomy Department 105-24, Caltech, Pasadena, California 91125, USA; phone +1-818-356-4980; FAX +1-818-568-9352; tjp@deimos.caltech.edu.
2. Haystack PC-SCHED: Contact A.E.E. Rogers, Haystack Observatory, Off Route 40, Westford, Massachusetts 01886, USA; phone +1-508-692-4764; FAX +1-617-981-0590; e-mail aeer@wells.haystack.edu.
3. NRAO AIPS: Contact AIPS Group, NRAO, 520 Edgemont Road, Charlottesville, Virginia 22903-2475, USA; aipsmail@nrao.edu.

25.2 Documents and Articles

A list of documents and articles referred to in this document follows. Copies of documents marked by an asterisk (*) are available from Betty Trujillo (see Section 25.4), while those marked by two asterisks (**) are available from Theresa McBride (see Section 25.4). Numerous articles from two books appear; abbreviations for these two books and complete references for them are as follows:

Very Long Baseline Interferometry = Very Long Baseline Interferometry: Techniques and Applications, edited by M. Felli & R.E. Spencer, Kluwer Academic Publishers.

Synthesis Imaging = Synthesis Imaging in Radio Astronomy, edited by R.A. Perley, F.R. Schwab, & A.H. Bridle, Astronomical Society of the Pacific Conference Series, volume 6.

25.3 VL AIS and Mosaic

There are two sources of on-line information about the VLBA. First, there is a simple information system, VL AIS, on the Zia computer system at the AOC. Access to this system is by Internet (address 146.88.1.4) or through the NRAO Socorro terminal switch (+1-505-835-7010). At the login message for Zia type vlais (no password required). A menu will list the major categories available. Choose VLBA to get to the VLBA specific information.

Second, NRAO-wide information is available via the NCSA Mosaic program. If you have mosaic available locally, use the URL <http://info.aoc.nrao.edu/> to point towards the NRAO Home Page. VLBA and AOC specific information are available from the Home Page.

25.4 Key Personnel

Table 6 gives the primary work locations, telephone extensions, room numbers, and area of responsibilities and/or expertise of key NRAO personnel who are available to assist the VLBA user community. An individual can be contacted through e-mail via their NRAO username constructed in lower case from their first initial followed by their last name, with a maximum of 8 letters. Address e-mail enquiries to username@nrao.edu via Internet, or to east::"username@nrao.edu" or 6913::"username@nrao.edu" via Span. Users on Bitnet should use the Internet address. In Table 6, "AOC" refers to

the Array Operations Center (phone +1-505-835-extension), “VLA” refers to the Very Large Array (phone +1-505-772-extension), and “CV” refers to Charlottesville (+1-804-296-extension).

Table 6: Resource List of Key Personnel

Name	Location	Extension	Room	Responsibilities and/or Expertise
Dave Adler	AOC	7272	208	AOC AIPS manager
Durga Bagri	AOC	7216	182	VLBA testing, systems engineer
Tony Beasley	AOC	7243	305	postdoctoral fellow
Larry Beno	AOC	7212	186	masers, time
John Benson	AOC	7399	366	VLBA correlator
Carl Bignell	AOC	7242	344	VLA/VLBA operations head
Bill Brundage	AOC	7120	188	frequency coordinator, RFI, electronics head
Barry Clark	AOC	7268	308	VLA/VLBA scheduler, on-line systems
Mark Claussen	AOC	7284	268	VLBI at VLA, spectral line
John Conway	AOC	7249	200	postdoctoral fellow
Tim Cornwell	AOC	7333	362	AOC computing and operations head
Bill Cotton	CV	0319	219	AIPS, linear polarization VLBI
Vivek Dhawan	AOC	7378	310	mm VLBI, RFI
Phil Diamond	AOC	7365	306	AIPS, spectral line VLBI
Chris Flatters	AOC	7208	208	AIPS, orbiting VLBI
Ed Fomalont	CV	0232	305	astrometry
Dale Frail	AOC	7338	373	pulsars, scattering
Miller Goss	AOC	7300	334	NRAO assistant director for VLA/VLBA
Kevin Healy	AOC	7239	204	VLA/VLBA data analyst
Phillip Hicks	VLA	4319	220	chief VLA operator
Eileen Latasa	AOC	7357	218	AOC visitor registration
Theresa McBride	AOC	7000	267	printed VLA/VLBA AOC user documentation
Peter Napier	AOC	7218	218	VLBA construction project head
George Peck	AOC	7136	160	recorder engineer
Peggy Perley	AOC	7239	204	VLBA Chief Operator
Susan Prewitt	AOC	7238	204	VLA/VLBA data analyst
Paul Rhodes	AOC	7256	192	VLBA site group head
Terry Romero	AOC	7315	330	AOC scientific services
Jon Romney	AOC	7360	304	VLBA correlator, space VLBI
Michael Rupen	AOC	7248	200	postdoctoral fellow
Rita Salazar	AOC	7300	338	printed VLA/VLBA user information
Dick Sramek	AOC	7394	328	AOC electronics and engineering head
Meri Stanley	AOC	7359	204	VLA/VLBA data analyst
Betty Trujillo	AOC	7231	252	keeper of VLBA memo series
Craig Walker	AOC	7247	314	VLBA testing, SCHED
Joan Wrobel	AOC	7392	302	VLBA documentation; VLBI at VLA
Gustaaf van Moorsel	AOC	7396	348	AOC computing head
Wes Young	AOC	7337	378	VLBA OBSERVE
